

ABSTRACT

A processing device for processing a composite component with at least a support device and a stamp pad having at least one operating head of a material-removing unit. The material-removing unit and the composite component are moved relative to one another by means of a handling unit controlled by a control unit whereby material is removed from the composite component. The stamp pad of the composite component is divided into several mutually spaced pad parts by means of a dividing gap, whereby the operating head together with a dispensing unit of an ink dispenser unit is incorporated in an effector unit.
